SCIENTIFIC COUNCIL MEETING – SEPTEMBER 2008

Division 3M Northern shrimp (*Pandalus borealis*) – Interim Monitoring Update

By

J.M. Casas Sánchez

Abstract

This document updates some of the indices for northern shrimp (*Pandalus borealis*) harvested within NAFO Divisions 3M. The assessment for this resource was completed, within Scientific Council during autumn 2007, and although it was not possible to present a management advice on a specific TAC due to insufficient information, in light of the poor prospect for this stock, the scientific council recommended that the exploitation level for 2008 and 2009 should not exceed the 2005 and 2006 levels. The catch table (to September 2008) and biomass estimates (EU survey summer 1988-2008) are updated within this report. Preliminary data indicate that 20 533 t and 16 869 t of shrimp were taken in 2006 and 2007 respectively against an annual TAC of 48 000 t. In the 2008 EU survey the 3M biomass index was 10 931 t, the lowest value of the last 10 years and confirm the decreasing trend initiated in 2002.

Fishery and Management

Effort and TAC regulation

During 2007 meeting, Scientific Council (NAFO 2007) noted there was insufficient information on which to base predictions of annual yield potential for this resource and was therefore unable to advise on a specific TAC for 2008 and 2009. However, in light of the poor prospect for this stock, the Scientific Council recommended that exploitation level for 2008 and 2009 should not exceed the 2005-2006 levels. This corresponds to catches in the range of 17,000 to 32,000 tons.

Catch trends

The fishery for northern shrimp at Flemish Cap began in the spring of 1993 and has since continued with estimated annual catches (as estimated by STACFIS, Table 1) of approximately 26 000 t to 48 000 t in the years 1993 through 1996. After 1996 catches were lower and rising slowly from 26 000 t in 1997 to 53 000 t in 2000 and 2001. There was 50 000 t taken in 2002. The catch increased in 2003, reaching the highest value in the catches series (64 000t), declining to about 21 000 and 17 000 t in 2006 and 2007 respectively. Removals to September 2008 (about 8 000 t) are similar to the reported in 2007 for the same period but much lower than usually reported in previous years.

UE Bottom Trawl Research Survey Trends

Summer multi-species research surveys have been conducted onboard the Spanish vessels R/V Cornide de Saavedra since 1988 and R/V Vizconde de Eza since 2003. From 1988 to 2002 the indexes estimated by the R/V Cornide de Saavedra were calibrated and transformed to the R/V Vizconde de Eza following the Warren's method. Fishing sets of 30 minute duration, with a tow speed of 3 knots, were randomly allocated to strata covering the Flemish Cap Bank to a depth of 1 462 m since 2004, with the number of sets in a stratum proportional to its size (Figure 2). Both vessels used the same gear (Lofoten) with a codend mesh size of 35 mm. In order to obtain information about the juvenile fraction of the stock, since 2001 a bag with 6 mm mesh size was attached to the cod-end of the Lofoten gear. SCANMAR sensors were employed to monitor net geometry. Details of the survey design and fishing protocols are outlined in (Casas, 2007).

The increasing of biomass since 1988 to 1992, coincided with a period of time where there was not a directed fishery to shrimp and the cod stock began to decline. With the beginning of the shrimp fishery in 1993 the biomass declined up to 1997. After that the stock recovered reasonably well although with high annual variability in the last years (historical maximums in 2002 and 2005 were followed by years with lower biomass but at a relative high level). The total and female biomass 11 171 t and 8 705 t respectively estimated in 2008 (Table 2), were the lowest values of biomass in the last ten years and about a 36 % lesser than the estimated in 2007, showing a decreasing trend in the biomass of this stock (Figure 3).

Biomass estimated by depth strata from 1988 to 2008 is shown in Table 3. The presence of shrimp in shallowest strata, with depths less than 140 fathoms (257 m), was scarce in the first years (1988-1995). However, since 1996, a noticeable amount of shrimp occurred in these strata and the estimated biomass increased up to 2002 year where 12 978 tons, about the 36 % of the total biomass were estimated in depths lesser than 140 fathoms. After 2002 the biomass estimated in these depths declined each year and in 2008 was residual (about 0.4 % of total biomass). In accordance with this, the catch distributions observed during the 2008 survey (Fig. 4) showed a distribution around the central area of the bank but in depths higher than in previous years.

As in the last years (2003-2007) the youngest specimens (age 1) didn't appear in the catches (Figure 5) , and they were weakly presents in the small mesh size bag attached to the cod-end, suggesting the absence of any strong year classes since 2003.

Considering the abundance at age 2 as indicator of recruitment, the number of shrimp of two years old in the survey and from juvenile bag (Figure 6) were estimated and the index average-weighted. Both indexes showed a similar trend with the exception of 2003 and 2006 years where the less marked changes showed different trends. From both indexes the 2003-2006 year class ought to be considered as weak year classes.

Conclusions

Preliminary data indicate that 7 971 t of shrimp had been taken in the 3M shrimp fishery by september 2008 and it is anticipated that the catch around 16 000 t would be taken by the end of December 2008.

The low values of the Total and Female biomass index in 2008 confirm the decreasing trend of this stock caused by the weak recruitment in the last four years. Based on the information available no change is proposed for the Scientific Council advice for which the exploitation level in 2009 should not exceed the 2005-2007 levels. This would correspond to catches in the range of 17 000 to 32 000 tons.
